Large Natural Avalanche on Emigrant Peak

Emigrant Peak Out of Advisory Area 2/3/2022 Code HS-N-R2-D2-O Elevation 10000 Aspect SE Latitude 45.25960 Longitude -110.70200 Notes

On Saturday, skiers on the SE <u>couloir</u> of Emigrant Peak found debris from a large natural avalanche. It appears to be more than 24 hours old.

From obs (2/5/22): "Attempted to ski the SE <u>Couloir</u> on Emigrant Peak today. As we approached, we noticed recent avalanche debris in the <u>runout zone</u> of the line. We approached carefully and it looked to be somewhat recent in the last few days. Not buried by much recent snow but also did not look fresh as of that day. I am guessing it was triggered by a collapsed <u>cornice</u> but with poor visibility it was challenging to see any sort of crown or broken <u>cornice</u> above us. We did not ski the <u>couloir</u>. I dug a pit in the open east facing bowl below at 9200 ft. The snowpack was between 55-75cm deep. In this location, the bottom 30cm of the snowpack were very large, well-developed facets with some <u>depth hoar</u>. I got ECTN 14 about 45cm up and ECTX on the facet/midpack interface (30cm up)."
